Evolution / Genetics / Biology Scientists leave an evolutionary footprint in genes Scientists have found "footprints" of evolution in the DNA of living organisms, reports the Scientific American. Dedicated evolution

enthusiasts were not entirely surprised by the findings, but evolutionary biology enthusiasts were stunned to find that researchers had discovered evidence that gave them at least a small glimpse into the evolutionary histories of species. The scientists discovered that human DNA had a similar chromosome structure to that of Neanderthals, suggesting that our common ancestor with the Neanderthals lived quite recently. The research, reported in the October issue of Science, was conducted by a team of Stanford University scientists and was published online this month. Previous research has suggested that our common ancestor with Neanderthals lived at least 160,000 to 200,000 years ago, but this study suggests that the line of descent may be more recent, and that humans and Neanderthals could have had a much closer common ancestor than previously thought. The study, conducted with Albert Zuckerkandl, a professor of pharmacology at Stanford University, revealed that the percentage of the genes shared between humans and Neanderthals was higher than the percentage shared with other primates. The scientists also concluded that, unlike other primates, humans have more of the same two chemical components of DNA than they b7e8fdf5c8

HDD Benchmark (6.40 MB) File Name: HDD Benchmark Date Added: Mar 14, 2012 File Size: 6.41 MB Price: Free Downloads: File Review: I recently decided to benchmark Windows 7 on my Core i7-870 processor. I had recently updated everything on my system and was pleased with how everything performed. Then I decided to benchmark on a new 500 gig hard drive. This was a hard drive I had just recently purchased to replace the worn out drive in my old system. I had an older motherboard (ASUS P8Z68-V PRO) that I had decided to upgrade to the ASUS P8Z68-V LE. Since this board was a little older and used an older version of Windows, I was thinking it might perform a little slower than the motherboard with the newer processor. It was an incredible difference. I have to admit, I was a little bit disappointed with my performance. It would have made me second guess my decision to upgrade. I did purchase a new HDD (Seagate Barracuda 500 gig) and installed it. I installed the Windows 7 Ultimate 32 bit version. The results were astronomical. Every thing I had benchmarked before was now faster. I was shocked. Even with the newer motherboard, I am getting close to the performance of my old motherboard with the old processor. My old board was giving me 150 MB/s read and 98 MB/s write. My new board is giving me 330 MB/s read and 206 MB/s write. You may think that is a little slow, but once you see this benchmark, you'll understand how everything was sluggish before. I would not recommend you upgrade your motherboard, but if you want to go this route
