I only included two rows for simplicity) X Y Z A B C D E 1 1 0.6 0.6 1 1 1 2 2 0.8 0.4 2 2 2 1 I would like to extract all rows and column that sums of row 1 is greater than or equal to 3. I'd like to get: X Y Z A B C D E 1 1 0.6 0.6 1 1 1 2 2 0.8 0.4 2 2 2 1 I've tried the following line but it can't be run on row 1 and column 1 of the entire dataframe df[df['A']>=3] I've also tried this line but only returns the row 1 df[df['X'].sum()>=3] If I were to sum all the columns the desired output would be: X Y Z A B C D E 1 1 0.6 0.6 1 1 1 2 2 0.8 0.4 2 2 2 1 Note 0cc13bf012

SolidWorks 2018 SP5 Full Premium Activator Serial Keyl.Printed circuit boards are widely used in the manufacture of computer and other electronic equipment. In particular, circuit boards are commonly used in components such as CPUs, memory chips, etc. The components include a plurality of connections that need to be made between the circuits of the boards. In a conventional printed circuit board, the individual printed circuit lines must be soldered to the surface of a circuit board in order to properly make the connections. There is a need to further reduce the cost of manufacturing the printed circuit board. One particular area of cost is in the ability to quickly solder chips onto a printed circuit board. In order to meet increasing demand for faster

processing and to reduce cost, recent developments in the board industry have focused on providing a through hole on the surface of a board through which a wire is inserted to provide electrical connection between circuits. Various types of through hole technology are well known in the art. The particular holes that are used depend on the distance between the through holes to be interconnected and the type of connection to be made. In order to make connections between two through holes, one of the holes is filled with solder paste so that when the solder paste is heated a wet solder connection is created. The second hole in which a wire is inserted is similarly filled with solder paste. The solder paste creates a solid state connection

When perceptual judgments about a target stimulus are made in the presence of a visual mask, the visibility of the target and the strength of masking influence the results. We investigated whether the results of such perceptual tasks are dependent on the spatial relationship between the target and the mask, and if so whether the similarity (congruence) or proximity (nearness) of spatial positions is more important in determining the results. To do this, neural representations of spatial relations between target and mask stimuli were mapped in the occipital cortex of human subjects. The spatial relationship between stimuli was varied by systematically varying their spatial locations or their orientations in visual space. The results showed that the pattern of cortical representation did depend on the spatial relationship between the target and the mask, indicating that the spatial relationship between target and mask influences the results of a perceptual task. Congruence (similarity) of spatial positions influenced the results more than proximity (nearness) of spatial positions did. Challenging and static nature of the surface of nanoparticles makes it easy to adhere to surfaces. They can adhere to many different

materials such as polymers, glasses and metals. Nanoparticles can also stick to each other and form structures, which can be coated with other materials to form composites. Having the need for new materials has resulted in many research studies using nanoparticles. The use of nanoparticles has shown promising results in applications such as cosmetics, medicine, construction, semiconductors, catalysts, etc. Nanoparticles can provide key benefits such as “nano-sizing” which can be helpful to enhance the properties, such as: solubility,
